EECS 127/227AT Optimization Models in Engineering Spring 2020 Homework 12

This homework is due Saturday, April 25, 2020 at 23:00 (11pm). Self grades are due Friday, April 31, 2020 at 23:00 (11pm).

This version was compiled on 2020-04-23 01:42.

Submission Format: Your homework submission should consist of a single PDF file that contains all of your answers (any handwritten answers should be scanned) as well as your IPython notebook with solutions saved as a PDF.

Note: This concepts covered in this homework are important for the final and you should still read and understand them despite the self-grade not being due till after the final.

1. Newton's Method, Coordinate Descent and Gradient Descent

In this question, we will compare three different optimization methods: Newton's method, coordinate descent and gradient descent. We will consider the simple set-up of unconstrained convex quadratic optimization; i.e we will consider the following problem:

$$\min_{\vec{x} \in \mathbb{R}^d} \vec{x}^\top A \vec{x} - 2 \vec{b}^\top \vec{x} + c$$

where $A \succ 0$ and $\vec{b} \in \mathbb{R}^d$.

(a) How many steps does Newton's method take to converge to the optimal solution? Recall that the update rule for Newton's method is given by the equation:

$$\vec{x}_{t+1} = \vec{x}_t - (\nabla^2 f(\vec{x}_t))^{-1} \nabla f(\vec{x}_t).$$

when optimizing a function f.

(b) Now, consider the simple two variable quadratic optimization problem for $\sigma > 0$:

$$\min_{\vec{x} \in \mathbb{R}^2} f(\vec{x}) = \sigma x_1^2 + x_2^2.$$

How many steps does coordinate descent take to converge on this problem? Assume that we start by updating the variable x_1 in the first step, x_2 in step two and so on; therefore, we will update x_1 and x_2 in odd and even iterations respectively:

$$(x_{t+1})_1 = \begin{cases} \operatorname{argmin}_{x_1} f(x_1, (x_t)_2) & \text{for odd t} \\ (x_t)_1 & \text{otherwise} \end{cases}$$
 and $(x_{t+1})_2 = \begin{cases} \operatorname{argmin}_{x_2} f((x_t)_1, x_2) & \text{for even t} \\ (x_t)_2. & \text{otherwise} \end{cases}$

Here, $(x_t)_2$ represents x_2 at time t and so on.

(c) We will now analyze the performance of coordinate descent on another quadratic optimization problem:

$$\min_{\vec{x} \in \mathbb{R}^2} f(\vec{x}) = \sigma(x_1 + x_2)^2 + (x_1 - x_2)^2.$$

where we have, as before, $\sigma > 0$. Note that (0,0) is the optimal solution to this problem. Now, starting from the point (1,1), how many steps does coordinate descent take to converge to (0,0). What happens when σ grows large? Hint: First find the update rule for x_1 , i.e. keep x_2 fixed and figure out how x_1 changes when t is odd. Then do the same for x_2 when x_1 is fixed.

(d) Finally, for the objective function from the previous part, how long does gradient descent take to converge to (0,0) starting from the point (1,-1)? Assume for this part that $\sigma > 1$ and reason about how many steps it takes for gradient descent to converge when σ grows large. Hint: What is the step size for gradient descent? Also note that f is given by:

$$f(\vec{x}) = \vec{x}^{\top} A \vec{x} \text{ where } A = 2 \left(\sigma \begin{bmatrix} \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} \end{bmatrix} \begin{bmatrix} \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{bmatrix} + \begin{bmatrix} \frac{1}{\sqrt{2}} \\ -\frac{1}{\sqrt{2}} \end{bmatrix} \begin{bmatrix} \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} \end{bmatrix} \right).$$

2. Gradient Descent vs Newton Method

Run the jupyter-notebook 'Gradient_vs_Newton.ipynb' which demonstrates differences between gradient descent and Newton's method.

3. (Optional) Ridge Regression Classifier Vs. SVM

In this problem, we explore Ridge Regression as a classifier, and compare it to SVM. Recall Ridge Regression solves the problem

$$\min_{\vec{w}} \|X\vec{w} - \vec{y}\|_2^2 + \lambda \|\vec{w}\|_2^2,$$

where $X \in \mathbb{R}^{m,n}$, and $\vec{y} \in \mathbb{R}^n$

- (a) Ridge Regression as is solves a regression problem. Given data $X \in \mathbb{R}^{m \times n}$ and labels $\vec{y} \in \{0,1\}^m$, explain how we might be able to train a Ridge Regression model and use it to classify a test point.
- (b) Complete the accompanying Jupyter Notebook to compare Ridge Regression and SVM.

4. Soft-margin SVM

Consider the soft-margin SVM problem.

$$p^{*}(C) = \min_{\vec{w} \in \mathbb{R}^{m}, b \in \mathbb{R}, \vec{\xi} \in \mathbb{R}^{n}} \frac{1}{2} \|\vec{w}\|_{2}^{2} + C \sum_{i=1}^{n} \xi_{i}$$
s.t. $1 - \xi_{i} - y_{i}(\vec{x}_{i}^{\top}\vec{w} - b) \leq 0, \quad i = 1, 2, ..., n$

$$-\xi_{i} \leq 0, \quad i = 1, 2, ..., n,$$

$$(1)$$

where $\vec{x}_i \in \mathbb{R}^m$ refers to the i^{th} training data point, $y_i \in \{-1,1\}$ is its label, and $C \in \mathbb{R}_+$ (i.e. C > 0) is a hyperparameter.

Let α_i denote the dual variable corresponding to the inequality $1 - \xi_i - y_i(\vec{x}_i^\top \vec{w} - b) \leq 0$ and let β_i denote the dual variable corresponding to the inequality $-\xi_i \leq 0$.

The Lagrangian is then given by

$$\mathcal{L}(\vec{w}, b, \vec{\xi}, \vec{\alpha}, \beta) = \frac{1}{2} \|\vec{w}\|_{2}^{2} + C \sum_{i=1}^{n} \xi_{i} + \sum_{i=1}^{n} \alpha_{i} (1 - \xi_{i} - y_{i} (\vec{x}_{i}^{\top} \vec{w} - b)) - \sum_{i=1}^{n} \beta_{i} \xi_{i}.$$

Suppose $\vec{w}^*, b^*, \vec{\xi}^*, \vec{\alpha}^*, \beta^*$ satisfy the KKT conditions.

Classify the following statements as true or false and justify your answers mathematically.

- (a) Suppose the optimal solution \vec{w}^*, b^* changes when the training point \vec{x}_i is removed. Then originally, we necessarily have $y_i(\vec{x}_i^\top \vec{w}^* b^*) = 1 \xi_i^*$.
- (b) Suppose the optimal solution \vec{w}^*, b^* changes when the training point \vec{x}_i is removed. Then originally, we necessarily have $\alpha_i^* > 0$.
- (c) Suppose the data points are strictly linearly separable, i.e. there exist \vec{w} and \tilde{b} such that for all i,

$$y_i(\vec{x}_i^{\top}\vec{\tilde{w}} - \tilde{b}) > 0.$$

Then $p^*(C) \to \infty$ as $C \to \infty$.

5. Linear Quadratic Regulator

In this question, we will derive the Riccati equation for the LQR model studied in class. We first recall the statement of the LQR problem:

$$\min_{\vec{x}_t, \vec{u}_t} \sum_{t=0}^{N-1} \frac{1}{2} \left(\vec{x}_t^\top Q \vec{x}_t + \vec{u}_t^\top R \vec{u}_t \right) + \frac{1}{2} \vec{x}_N^\top Q \vec{x}_N$$

$$\text{s.t } \vec{x}_{t+1} = A \vec{x}_t + B \vec{u}_t$$

$$\vec{x}_0 = \vec{x}_{\text{init}}$$

where \vec{x}_t is thought of as the state of the system and \vec{u}_t is the control input at time t and the matrices A and B define the dynamics of the system. While the problem can be solved as a quadratic program, we will now take a slightly different approach. We start by defining the functions, J_k for $0 \le k \le N$, as follows:

$$J_{k}(\vec{x}) = \min_{\{\vec{u}_{t}\}_{t=k}^{N-1}} \sum_{t=k}^{N-1} \frac{1}{2} \left(\vec{x}_{t}^{\top} Q \vec{x}_{t} + \vec{u}_{t}^{\top} R \vec{u}_{t} \right) + \frac{1}{2} \vec{x}_{N}^{\top} Q \vec{x}_{N}$$
s.t $\vec{x}_{t+1} = A \vec{x}_{t} + B \vec{u}_{t}$

$$\vec{x}_{k} = \vec{x}.$$

 J_k can be thought of as the minimum cost that we would incur from time k assuming that we start at state $\vec{x}_k = \vec{x}$. We can now decompose J_k for $0 \le k \le N - 1$ further as follows:

$$J_k(\vec{x}) = \min_{\vec{u}_k} \frac{1}{2} \left(\vec{x}_k^\top Q \vec{x}_k + \vec{u}_k^\top R \vec{u}_k \right) + \min_{\substack{\{\vec{u}_t\}_{t=k+1}^{N-1} \\ t=k+1}} \sum_{t=k+1}^{N-1} \frac{1}{2} \left(\vec{x}_t^\top Q \vec{x}_t + \vec{u}_t^\top R \vec{u}_t \right) + \frac{1}{2} \vec{x}_N^\top Q \vec{x}_N$$
s.t $\vec{x}_{t+1} = A \vec{x}_t + B \vec{u}_t$

$$\vec{x}_k = \vec{x}.$$

Note that in particular, the first constraint implies that $\vec{x}_{k+1} = A\vec{x}_k + B\vec{u}_k$. Therefore, the above characterization gives the following decomposition:

$$J_k(\vec{x}) = \min_{\vec{u}} \frac{1}{2} \left(\vec{x}^\top Q \vec{x} + \vec{u}^\top R \vec{u} \right) + J_{k+1} (A \vec{x} + B \vec{u}).$$
 (2)

We will see that the functions, J_k , are all in fact quadratic functions in \vec{x} and this will give us convenient ways to derive the optimal control inputs at each time.

(a) First, we will show by reverse induction that each of the functions J_k for $0 \le k \le N$ are convex quadratics. In particular, prove that $J_k(\vec{x}) = \vec{x}^{\top} \frac{Q_k}{2} \vec{x}$ for some $Q_k \succ 0$ and determine the value of Q_k in terms of Q_{k+1} .

Hint 1: $J_N(\vec{x}) = \frac{1}{2}\vec{x}^\top Q\vec{x}$. Therefore, $Q_N = Q$. Also can use (2) above, and substitute $J_{k+1}(A\vec{x} + B\vec{u}) = (A\vec{x} + B\vec{u})^\top Q_{k+1}(A\vec{x} + B\vec{u})^\top$. Then solve the resulting QP to find the optimal \vec{u} .

Hint 2: You should get the following recursion for Q_k :

$$Q_k = Q + A^{\mathsf{T}} Q_{k+1} A - A^{\mathsf{T}} Q_{k+1} B (R + B^{\mathsf{T}} Q_{k+1} B)^{-1} B^{\mathsf{T}} Q_{k+1} A.$$

(b) (Optional) Now, show that the expression for Q_l is equivalent for the expression obtained by using the Lagrangian. That is, show that Q_l from the previous part is the same as:

$$Q_l = Q + A^{\top} (Q_{l+1}^{-1} + BR^{-1}B^{\top})^{-1}A.$$

You may find useful the Sherman-Morrison-Woodbury matrix identity:

$$(M + UWV)^{-1} = M^{-1} - M^{-1}U(W^{-1} + VM^{-1}U)VM^{-1}.$$
